Brainstorming and Ideation

Problem Identification.

The first step in developing the Auto Ticket Classification system is to identify the existing problem in the IT Helpdesk process. In a school or college environment, the IT Helpdesk receives many incident requests from students and teachers. These requests may be related to **Wi-Fi problems, password issues, hardware problems, slow computers, and other IT-related issues**.

Currently, **IT staff manually review each incident ticket and identify the appropriate and Subcategory**. They need to read the Short Description and Description of the incident before deciding how the ticket should be classified. When the number of tickets increases, this manual process requires more time and effort.

Manual classification can also result in incorrect or inconsistent category selection. This may affect ticket routing and the time required to resolve the issue. Therefore, there is a need for a simple and automated method to classify incident tickets.

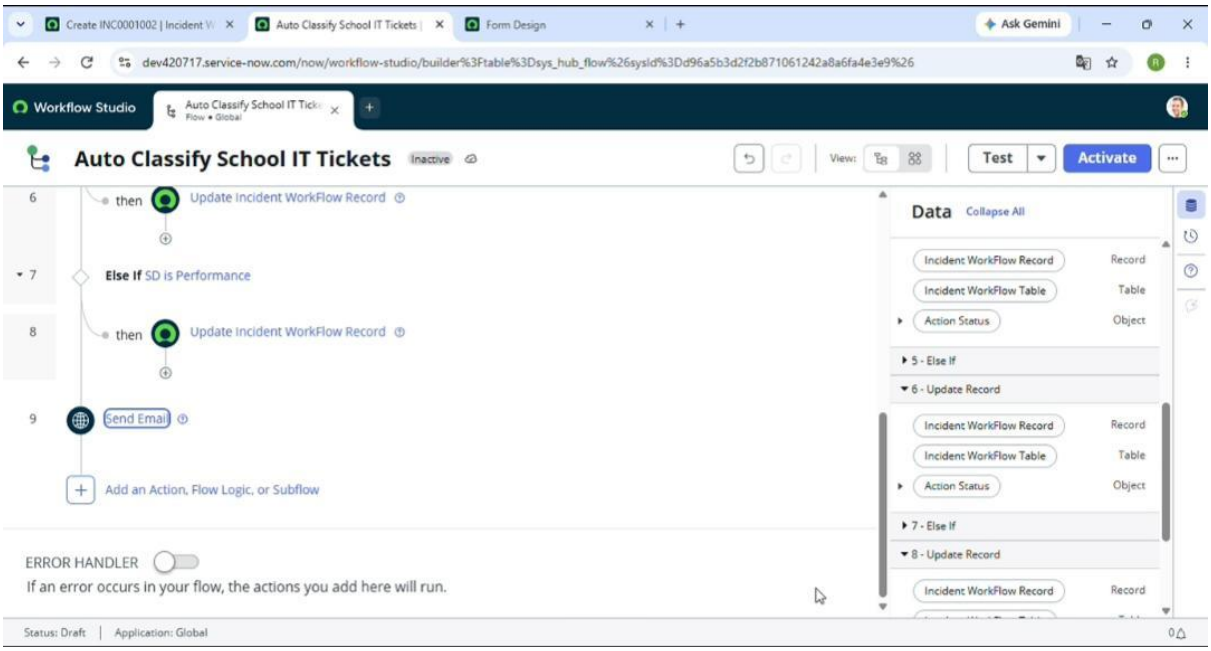

The identified problem is that **manual ticket classification requires additional time and effort from IT staff and may lead to human errors**.

Idea Generation.

After identifying the problem, different possible solutions were considered. The main purpose of **brainstorming was to find a simple and practical way to reduce the manual effort involved in incident classification**.

One possible solution was to continue with manual classification by IT staff. However, this would not reduce the existing workload. Another idea was to use predefined keywords from the incident description to automatically identify the type of issue.

Another possible idea was to use ServiceNow Flow Designer to automate the classification process. Flow Designer can be used to create a flow that checks the information entered in an Incident and performs the required actions automatically. Automated email notification was also considered so that the caller can be informed after the ticket is created.

The main idea selected from the brainstorming process was to use **ServiceNow Flow Designer for automatic ticket classification**. The flow can check keywords in the Short Description and Description and automatically assign the appropriate Category and Subcategory.

For example,

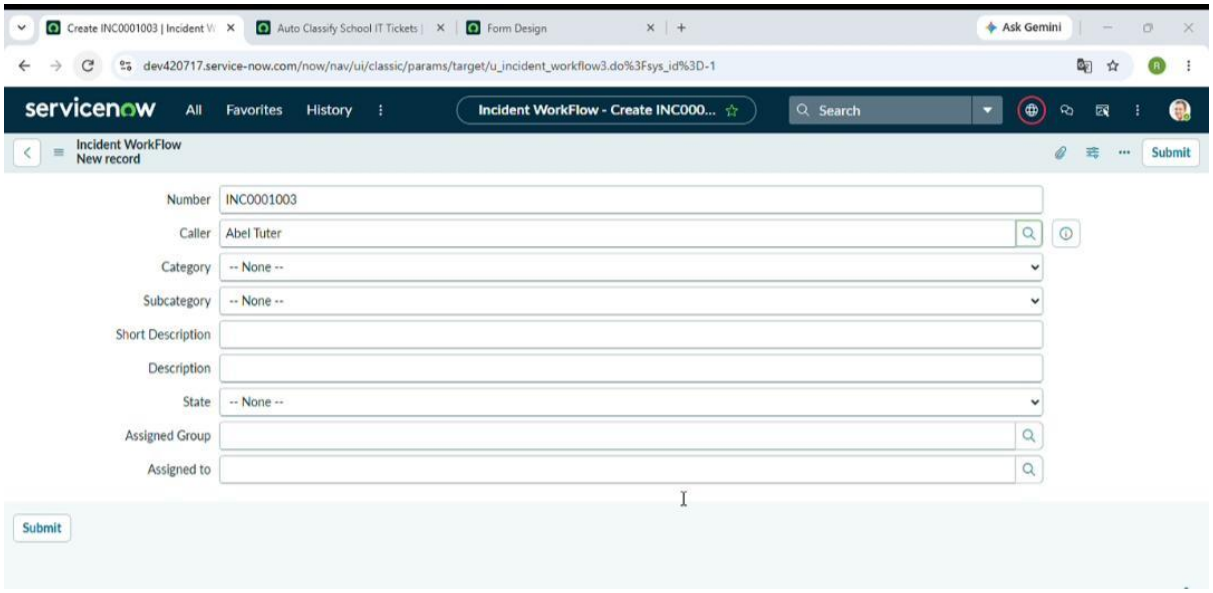

Incident Description: “My Wi-Fi is not working.”

Keyword: Wi-Fi

Category: Network

Subcategory: Wi-Fi

Selected Idea and Proposed Solution.

After considering the different possible solutions, ServiceNow Flow Designer was selected for implementing the Auto Ticket Classification system. The selected idea focuses on reducing manual classification and providing a simple automated process.

The proposed solution starts when a new Incident is created. The flow checks the Short Description and Description of the Incident. It looks for predefined keywords related to different IT issues. Based on the identified keyword, the flow automatically updates the Category and Subcategory fields according to the classification rule.

Example:

When a user creates an Incident with the description "**My Wi-Fi is not working**", the flow identifies the keyword "**Wi-Fi**".

The system can then assign:

- **Category**: Network
- **Subcategory**: Wi-Fi

Basic Proposed Flow:

- **Incident Created**
- **Check Description**
- **Identify Keyword**
- **Set Category**
- **Set Subcategory**
- **Send Email**

This approach provides a simple way to automate the classification process while keeping the solution easy to maintain and extend.

The selected solution is therefore designed to reduce manual work, improve consistency in ticket classification, and make the IT Helpdesk process more efficient.
