Project Documentation Phase

1. Project Title

Auto Ticket Classification using Flow Designer

Platform: Service now

Core Technology: Flow Designer

The project focuses on automating the classification and routing of tickets in Service now using Flow Designer.

2. Project Objective

The main objective of this project is to automate the initial classification of tickets using predefined business rules.

The objectives are:

To automate initial ticket classification.

To use Flow Designer to evaluate ticket data.

To reduce repetitive manual updates during ticket triage.

To route tickets to the appropriate category, priority, or assignment group.

To create a workflow that is easy to test, monitor, and extend.

To maintain clear classification logic and test scenarios.

3. Problem Statement

In the manual ticket-handling process, service desk personnel need to read ticket descriptions, select classification fields, identify the responsible support group, and perform similar updates repeatedly.

When the number of tickets increases, this process becomes

difficult to scale. Manual decisions can also result in inconsistent classification and routing.

Therefore, the project aims to create a repeatable automated workflow that examines ticket information and automatically applies predefined classification and routing rules inside.

4. Requirements

Hardware / Environment Requirements

Computer or laptop

Internet connection

Web browser

Access to a Service Now instance

Software Requirements

Service Now Platform

Flow Designer

ServiceNow ticket/incident records

ServiceNow data fields

Test data

Functional Requirements

The system should:

Accept a valid ticket record.

Evaluate the required classification fields.

Apply the configured rule when a condition is satisfied.

Update the required record fields or assignment information.

Maintain a workflow result for testing and troubleshooting.

Non-Functional Requirements

The system should be usable by authorized ServiceNow users.

Classification rules should be maintainable.

Workflow execution should be predictable.

Test cases should be repeatable and documented.

5. Project Design

The project follows an event-driven workflow design.

Workflow

Actions

↓

Update / Route Ticket

The ticket provides the required information. Flow Designer receives the trigger and evaluates the relevant ticket fields.

Based on the configured conditions, the workflow selects the appropriate classification path and updates or routes the ServiceNow record.

Flow Designer Stages

Trigger – Starts the flow when the required ticket event occurs.

Get / Read Data – Reads the fields required for classification.

Decision / Conditions – Compares ticket values with classification rules.

Actions – Updates category, subcategory, priority, assignment group, etc.

Notification / Follow-up – Optionally notifies a team or starts another workflow.

End / Logging – Completes the flow and provides a result for validation.

6. Development Process

The project can be developed using the following steps:

Step 1 – Identify the Ticket Table

Select the ServiceNow table containing the tickets to be classified.

Step 2 – Define Classification Fields

Identify the ticket fields that will be used as inputs and the fields that need to be updated.

Step 3 – Create the Flow

Create a new Flow in ServiceNow Flow Designer and provide a suitable name.

Step 4 – Configure the Trigger

Select the ticket event that should start the classification process.

Step 5 – Add Conditions / Decisions

Define the classification rules and the expected result for each branch.

Step 6 – Add Actions

Configure record updates, assignment, notifications, or follow-up activities.

Step 7 – Save and Test

Test each flow path using controlled ticket records.

Step 8 – Monitor Results

Review Flow Designer execution details and correct any rule or data issues.

7. Testing

Testing is performed to verify that the flow responds correctly to different ticket inputs.

Test ID

Scenario

Expected Result

T01

New ticket matching Rule 1

Correct category/routing

T02

New ticket matching Rule 2

Correct category/routing

T03

Ticket matching hardware rule

Hardware classification and assignment

T04

High-impact and high-urgency ticket

Configured priority is applied

T05

Ticket matching no rule

Default/manual-review path

T06

Existing ticket update

Flow starts only when trigger conditions are satisfied

T07

Invalid/incomplete input

No unintended update

Validation

Verify that the flow is active.

Verify that the trigger is configured correctly.

Verify each decision branch.

Verify the final ticket contains the expected values.

Verify unmatched tickets follow the default path.

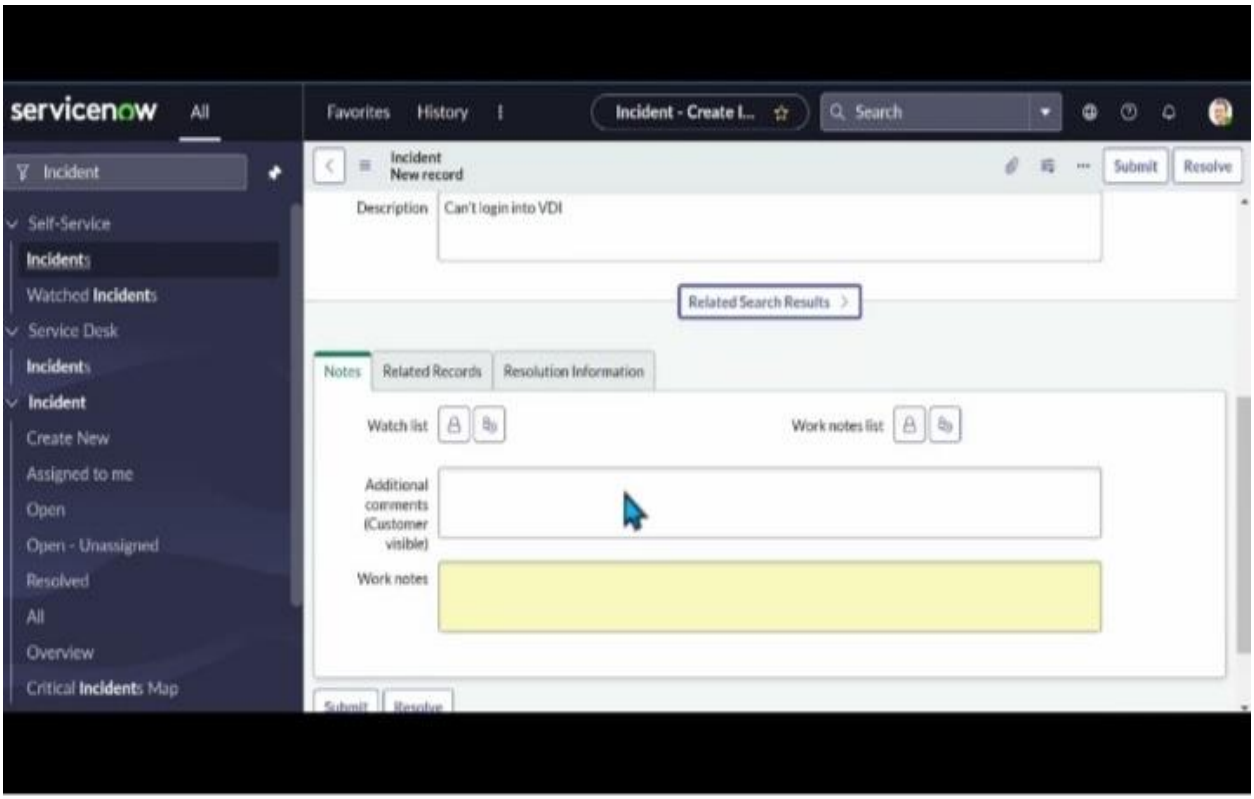

Review Flow execution details for failures or skipped actions.

Final updated ticket

9. Final Output

The final output is an automated ServiceNow workflow that classifies and routes tickets according to predefined rules.

The expected output includes:

Ticket classification is automatically updated.

Eligible tickets are assigned to the configured support group.

Equivalent ticket inputs produce consistent classification.

Classification rules can be modified when requirements change.

Flow execution details can be reviewed for failures or incorrect behavior.

Final Workflow Output

Ticket Created/Updated

→ Flow Triggered

→ Ticket Data Evaluated

→ Classification Rule Applied

→ Ticket Updated

→ Ticket Routed/Assigned

10. Benefits

The project provides the following benefits:

Reduces repetitive manual classification work.

Improves consistency in ticket routing.

Reduces manual effort during initial ticket triage.

Provides a visual workflow that is easier to understand and maintain.

Supports automation as ticket volume increases.

Makes workflow execution easier to monitor.

Allows classification rules to be extended when requirements change.

11. Conclusion

Auto Ticket Classification using Flow Designer demonstrates how ServiceNow workflow automation can be used to automate an important part of the initial service desk process.

By combining triggers, conditions, decision logic, and actions, the proposed solution can standardize ticket classification and routing.

The project provides a structured foundation for testing, monitoring, and future enhancement.

The final implementation depends on clear business rules, representative ticket data, correct Flow Designer configuration, and proper testing.
