3. PROJECT DESIGN PHASE

The Project Design Phase focuses on designing the overall structure and workflow of the **“Auto Ticket Classification using FLOW DESIGNER”** project. The main objective is to create an automated process that can identify and classify incoming tickets based on their details.

In this project, **FLOW DESIGNER** is used to create the automation flow. When a new ticket is created, the flow automatically reads ticket information such as category, description, priority, and other required fields. Based on predefined conditions, the ticket is classified into the appropriate category and routed to the corresponding group.

System Design

No.	Component	Description
1	**Ticket Creation**	A new ticket is created in the ServiceNow system.
2	**Trigger**	The Flow Designer flow starts automatically when a new ticket is created.
3	**Ticket Data Collection**	The flow collects important information from the ticket.
4	**Classification**	The ticket is classified according to predefined conditions.
5	**Assignment**	The classified ticket is assigned to the appropriate group or department.
6	**Notification**	A notification can be generated after successful classification and assignment.
7	**Ticket Update**	The ticket record is updated with the required classification and assignment details.

Flow Design

The basic workflow of the project is shown below. FLOW DESIGNER implements this process using triggers, actions and conditions, reducing manual work and providing a consistent method for handling tickets.

New Ticket	→	**Trigger**	→	**Read Ticket Details**	→	**Check Conditions**	→	**Classify Ticket**	→	**Assign Group**	→	**Update Ticket**	→	**Notification**

3. PROJECT DESIGN PHASE – CONTINUED

Flow Design – Detailed Process

1. New Ticket

A user or support process creates a new ticket in ServiceNow.

2. Trigger

The Flow Designer trigger detects the newly created ticket and starts the automation.

3. Read Ticket Details

The flow reads required fields such as category, description, priority and other ticket information.

4. Check Conditions

Predefined conditions are checked to identify the type and required handling of the ticket.

5. Classify Ticket

The ticket is classified into the appropriate category based on the conditions.

6. Assign Group

The classified ticket is automatically routed to the relevant support group or department.

7. Update Ticket

The ticket record is updated with classification and assignment details.

8. Notification

A notification can be generated to inform the relevant users or support team.

User Interface Design

The system uses the ServiceNow interface for creating and managing tickets. The user enters the required ticket details, while the automated flow performs classification and assignment in the background. This separates user input from the automated processing and makes the ticket-handling process easier to manage.

Design Architecture

USER	→	**SERVICENOW TICKET**	→	**FLOW DESIGNER**
Creates ticket		Stores ticket details		Trigger + Conditions + Actions
	→		→	**Classification** → **Assignment** → **Update** → **Notification**

Expected Design Outcome

The designed system should automatically classify tickets with minimum manual intervention. It should improve the organization of tickets, reduce processing time, and ensure that tickets are directed to the appropriate support team. The use of FLOW DESIGNER also provides a repeatable and consistent workflow for ticket classification and assignment.

Conclusion

The Project Design Phase defines the structure, components and workflow required for automated ticket classification. By combining ServiceNow ticket management with FLOW DESIGNER automation, the project provides a clear process from ticket creation to classification, assignment, update and notification.
